Indirect taxes less subsidies	3.1	7.5	0.4	0.9
Gross domestic product	2.3	9.8	2.3	9.8

Gross domestic product (GDP) increased in March quarter 1990 by 1.8 per cent in constant price seasonally adjusted terms.

In current price seasonally adjusted terms, GDP grew by 2.3 per cent. The major contributors to this growth were:

- a 2.1 per cent increase in wages, salaries and supplements, caused mainly by a rise in the underlying average earnings of 1.9 per cent (see *Average Weekly Earnings, Australia, February 1990, Preliminary* (6301.0) for details);
- an increase in gross operating surplus of 3.9 per cent for private corporate trading enterprises, mainly attributed to the strong growth in mining industry profits; and
- a 3.1 per cent rise in indirect taxes less subsidies.

The strong rise in mining industry gross operating surplus (see *Company Profits, Australia, March Quarter 1990* (5651.0)) is associated with increased production of petroleum and liquefied natural gas and, to a lesser extent, coal. Exports of these commodities grew significantly in the March quarter, with seasonally adjusted exports of coal, coke and briquettes increasing by 20.6 per cent in constant price terms and other mineral fuels (i.e. petroleum and liquefied natural gas) rising even more rapidly, recording growth of 62.7 per cent (see Tables 59 and 60 for details).

The rise in net indirect taxes was mainly due to higher than usual collections of franchise taxes on gas and petroleum products, sales taxes and excise taxes (see Table 27).

Comparing the change in current and constant price estimates of GDP (2.3 per cent and 1.8 per cent) implies

a price change of 0.4 per cent, but the increase in the implicit price deflator (IPD) for gross national expenditure (GNE) is 1.4 per cent (see Table 4). This significant difference is caused by changes in the composition of exports and imports of goods and services (see the section below headed *Implicit price deflators for exports and imports*). However, there would have been a strong growth in constant price seasonally adjusted GDP even in the absence of the compositional effects in the net trade component. The fixed-weighted price index for GDP rose by 0.9 per cent (see Table 11) which, when combined with growth of 2.3 per cent in current price

GDP, implies an increase in constant price GDP of about 1.4 per cent in the absence of any compositional changes.

The growth of 0.9 per cent in seasonally adjusted constant price private final consumption expenditure during March quarter 1990 was entirely due to strong growth in the non-retail sales components. In particular, fares rose by 6.0 per cent from the relatively low level recorded in December quarter 1989 during the height of the pilots' dispute, and purchase of motor vehicles increased by 7.0 per cent over December quarter (see Table 19).

NOTES ON THE ESTIMATES

Revisions in this issue

Revisions since the December quarter 1989 issue of this publication are shown in Tables 37 to 42. Revisions to major summary aggregates in constant price seasonally adjusted terms were relatively small for recent quarters. In particular, the December quarter 1989 estimate of growth in constant price seasonally adjusted GDP has been revised from -0.2 per cent to -0.1 per cent, while the growth in gross non-farm product for that quarter has been revised from -0.4 per cent to -0.2 per cent.

Exports of goods and services were revised down for December quarter 1989 by \$328 million at current prices (\$352 million at average 1984-85 prices) because of the incorporation of the latest available recorded trade data.

Seasonally adjusted estimates of stocks held by public marketing authorities have been revised for the last two quarters mainly because of the change to seasonal adjustment procedures described below under *Changes in this issue*.

Changes in this issue - Balance of payments tables, and Australian Wool Corporation stocks

Detailed tables for components of exports and imports of goods and services have been included in this publication because *Balance of Payments, Australia* (5302.0) is not expected to be released until 10 June 1990.

There has been a rapid rise in Australian Wool Corporation (AWC) stock levels in the past three quarters. As a result, the seasonal adjustment of this component of *increase in stocks* has been changed from September quarter 1989 because existing seasonal adjustment procedures were not able to cope with the rapid changes occurring. The seasonally adjusted estimates in both current and constant price terms for the last three quarters have been made identical to the unadjusted estimates. The reason for adopting this procedure is that the contribution of seasonal effects to the increase in AWC stocks is uncertain but is considered to be insignificant compared with the overall growth in AWC stocks in those quarters.

Implicit price deflators for exports and imports

The IPDs for exports and imports of goods and services were both affected significantly by compositional changes during March quarter 1990. The IPD for total exports fell by 3.2 per cent in March quarter compared with a decline of only 0.5 per cent in the fixed-weighted

price index (FWI). The corresponding changes for imports of goods and services were an increase of 1.9 per cent in the IPD and a rise of 0.8 per cent in the FWI.

The negative effects of compositional change observed for exports are attributable to some components with relatively low IPDs increasing their share of total exports and components with relatively high IPDs suffering a fall in their overall share. In March quarter 1990, major contributors to the compositional effects in the exports IPD were:

- cereals and cereal preparations which has a lower than average IPD (118.5 in March quarter compared with 125.3 for total exports of goods and services) and for which the constant price value increased by 31.7 per cent in seasonally adjusted terms in March quarter;
- wool and sheepskins (IPD level of 176.2 and a decline in exports of 29.2 per cent);
- coal, coke and briquettes (IPD level of 105.0 combined with an increase in exports of 20.6 per cent); and
- other mineral fuels (IPD level of 66.2 and a large rise of 62.7 per cent in exports).

For imports, the components for which compositional effects were most marked were fuels and transport equipment. Imports of fuels (which had an IPD of 75.6 in March quarter 1990 compared with 120.6 for total imports of goods and services) declined by 28.1 per cent in real terms. On the other hand, imports of transport equipment, which had a relatively high IPD (134.7) increased by 29.6 per cent during the quarter. The net effect of the compositional changes was to raise the growth in total imports prices from 0.8 per cent (as measured by the fixed-weighted price index) to the 1.9 per cent recorded in the IPD.

Terms of trade

Initial estimates indicate that Australia's terms of trade fell by 5.0 per cent in March quarter 1990, reflecting a decline in export prices of 3.2 per cent and a rise in import prices of 1.9 per cent. The implicit price deflators for both exports and imports of goods and services were affected by compositional change, with exports of goods being particularly affected (see notes above under the heading *Implicit price deflators for exports and imports*).

Movements in Australia's terms of trade are shown in the graph below.

Alternative measures of gross domestic product

There are three approaches which can be used to measure gross domestic product (GDP):

- the income approach, GDP(I), which involves summing factor incomes, consumption of fixed capital (depreciation) and net indirect taxes;
- the expenditure approach, GDP(E), which involves summing all final expenditure (plus exports less imports); and
- the production approach, GDP(P), which is generally applied at the industry level, and involves taking the market value of goods and services produced by an industry (i.e. gross output) and deducting the cost of goods and services used up by the industry in the productive process (i.e. intermediate consumption).

The difference between GDP(I) and GDP(E) at current prices is termed the 'statistical discrepancy'. It is included as a component of GDP(E). Its inclusion on the expenditure side of the domestic production account is a convention and does not necessarily imply that GDP(I) is a more accurate measure of production than GDP(E) (excluding the statistical discrepancy). However, it is apparent that the expenditure estimates have been more volatile than the income estimates at various times over the past 30 years.

Quarterly estimates of GDP(I) at current and constant (average 1984-85) prices are presented each quarter in this publication, while quarterly estimates of GDP(E) at current and constant prices can be readily derived by deducting the statistical discrepancy from GDP(I). Quarterly estimates of GDP(P) at constant prices are published in *Australian National Accounts: Gross Product, Employment and Hours Worked* (5222.0). GDP(P) is compiled a little later than GDP(I) and

GDP(E), and so 5222.0 is usually released a few weeks after this publication.

In concept, the 3 measures are identical but, in practice, they can differ significantly, particularly in the short term. The main reasons for the differences are that different data sources are used for each of the 3 approaches. As a result, it is possible for the aggregate measures derived using the various approaches to differ slightly.

The following tables provide a comparison of quarterly movements in recent years using each approach to measuring GDP.

PERCENTAGE CHANGES IN
GDP AT AVERAGE 1984-85 PRICES

Gross domestic product (GDP) at constant prices, adjusted for the terms of trade

Changes in the aggregate 'gross domestic product at constant prices' provide an indication of changes in the volume of goods and services produced within Australia. If, however, the terms of trade have changed significantly over the period of comparison the aggregate will not provide an accurate reflection of the change in the real purchasing power of the income generated by domestic production. Since June quarter 1988 the level of GDP adjusted for the terms of trade has been higher than the level of unadjusted GDP. However the rate of growth of GDP adjusted for the terms of trade has been lower than

that for the unadjusted GDP estimates in 3 of the last 4 quarters with the March quarter 1990 estimate rising by only 0.9 percent compared with 1.8 percent growth in the unadjusted estimate.

The following graph shows constant price GDP before and after adjustment for the terms of trade effect.

**GDP AT AVERAGE 1984-85 PRICES
(ADJUSTED FOR TERMS OF TRADE EFFECT)
SEASONALLY ADJUSTED**

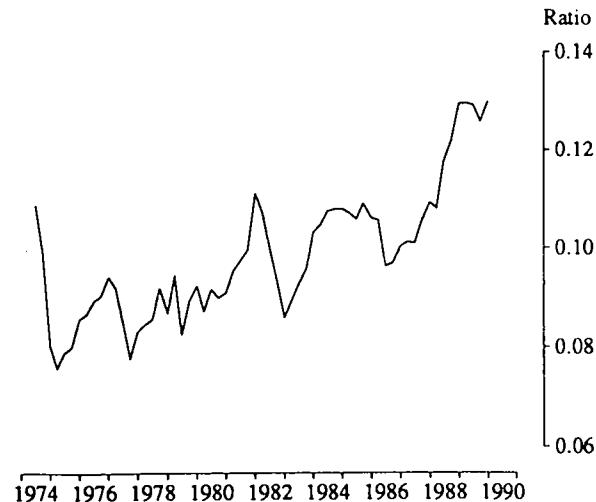

Imports to sales ratio

The imports to sales ratio (see paragraph 22 of the 'Explanatory Notes') rose to 0.130 in March quarter 1990 from 0.126 in the previous quarter. This was associated with a increase in endogenous imports of 5.2 per cent and an increase in sales of 1.8 per cent - both measured in seasonally adjusted constant price terms.

The ratio of imports to sales is graphed below.

**RATIO OF IMPORTS TO SALES
AT AVERAGE 1984-85 PRICES
SEASONALLY ADJUSTED**

Release date for June Quarter 1990 issue

The expected release time for the June quarter 1990 issue of *Australian National Accounts: National Income and Expenditure* (5206.0) is 7.30 pm on Commonwealth Budget night.

EXPLANATORY NOTES

Introduction

This publication provides estimates of the components of gross domestic product and national expenditure and supporting tables for the March quarter 1990, together with comparative estimates for the eight previous quarters and the four years 1985-86 to 1988-89. In addition, seasonally adjusted estimates of the major aggregates and some selected series are provided for the March quarter 1990, together with comparative estimates for the twelve previous quarters. Tables 37-42 show revisions that have been made to major aggregates since the previous publication. Tables 43-55 provide time series, in both original and seasonally adjusted terms, for the period from September quarter 1974 for the aggregates contained in the domestic production account (at both current and average 1984-85 prices), some income aggregates, implicit price deflators and some other selected series. Detailed trade data are provided in Tables 56-62.

Concepts, definitions, sources and methods

2. An expanded version of *Australian National Accounts: Concepts, Sources and Methods* (5216.0) has just been released. It outlines major concepts and definitions, describes sources of data and methods used to derive annual and quarterly estimates for major aggregates at both current and constant prices and discusses the accuracy and reliability of the national accounts. In addition it now includes documentation on input-output tables, flow of funds tables, capital stock and State accounts.

Interpretation of quarterly estimates

3. Estimating for a period of less than one year presents special problems in that it is often difficult to adhere strictly to the definitions and concepts used in annual estimates. The measurement of income for a quarterly period is particularly difficult since it is not always possible to match the value of production for a quarter with the cost incurred in that production. This problem occurs, for example, in estimating the income of farm unincorporated enterprises in each quarter and results in considerable variation in estimates for this series, and for gross farm product, from quarter to quarter. Difficulties are also experienced in obtaining detailed data for short periods and in preparing consistent estimates from various sources where different accounting procedures and periods are used.

4. These problems inevitably affect the consistency and reliability of the current price estimates, and similarly affect the constant price estimates based on the current price estimates. Accordingly, these factors as well as the approximations and assumptions necessarily made in the revaluation of flows to constant prices should be taken into account when interpreting or using the estimates (for example, in attempting to draw precise quantitative inferences relating to quarter-to-quarter changes in gross domestic product or its components, or in measuring productivity).

5. Analysis of trends requires allowance for these uncertainties in estimation. To some extent, the effects are indicated by the changes in the statistical discrepancy for corresponding periods. Uncertainty in trends arises also from the likelihood of revisions as more information becomes available and from the irregularity of short-term movements. The inclusion of the statistical discrepancy on the expenditure side of the accounts is a convention and does not necessarily imply that the sum of income components more accurately measures GDP than the sum of the expenditure components (plus exports less imports). As household and other saving are estimated as balancing items in their respective accounts, care should be exercised in their interpretation.

6. Estimates of national income and expenditure are necessarily prepared from a wide range of statistical information, some of which is available quickly and some only with a delay of several years. For this reason most figures should be regarded as subject to revision as more complete and more accurate information becomes available. The revisions will be of two main types - those made to the most recent quarters as firmer quarterly or monthly data come to hand and those which are a consequence of revisions to annual totals and distributed to the quarters approximately in accordance with existing quarterly patterns.

7. No simple measure is available of the accuracy of the major summary national accounting aggregates. However, the following example illustrates the *sensitivity* of quarter-to-quarter growth to the timing of recording a transaction. If, in the latest year, the timing of recording a transaction were delayed by one quarter and if the transaction had an impact on constant price gross domestic product of +\$64 million then the measure of the rate of growth would be affected in the three adjoining quarters (centred on the quarter in which the transaction was recorded) by -0.1, +0.2, and -0.1 percentage points respectively. Of course the percentage impact of such a timing delay on relevant sub-aggregates would be greater.

8. The quarterly implicit price deflators (IPDs) shown in Table 9 are derived by dividing seasonally adjusted current price estimates by the corresponding seasonally adjusted constant price estimates. Movements in the levels of individual implicit price deflators can be greatly affected by changes in the physical composition of the aggregates and their components. Generally, it is considered that IPDs derived from seasonally adjusted data are more reliable than those obtained by using original (i.e. unadjusted) series, because the former are less likely to be affected by compositional change than are the latter. However the seasonal adjustment process is itself a source of possible distortion, especially to the extent that it is not possible to identify, in a fully consistent way, the seasonality of the current price estimates and of the constant price estimates. A discussion of the limitations involved in using IPDs as measures of pure price change is contained in Appendix

B of Australian National Accounts: Concepts, Sources and Methods (5216.0).

Seasonal adjustment

9. As most series are affected to some extent by seasonal factors, allowance should be made for normal seasonal variation. In a number of tables, *seasonally adjusted* values are presented for selected series. Series which show substantial irregularities in the original or adjusted series should be treated with some reserve. As different methods of seasonal adjustment tend to produce different results, it is necessary to take into account the methods by which seasonally adjusted estimates have been derived and the limitations to which those methods are subject. It should also be noted that the methods of seasonal adjustment used by the ABS do not force the sum of the seasonally adjusted estimates for each quarter of a financial year to equal the original annual total.

10. The general methods used in the ABS for making seasonal adjustments are described in *Seasonally Adjusted Indicators, Australia 1983* (1308.0). However, special methods have been used to adjust some of the components of gross farm product which were not amenable to seasonal adjustment by the usual methods. To obtain these seasonally adjusted estimates, the estimated values of production of wheat, other grain and sugar cane, for any financial year, are distributed equally over the four quarters of the year ended June. One effect of this method is that changes in the annual production of these commodities enter into the seasonally adjusted figures in the September quarter.

11. Where there is no apparent seasonality in their implicit price deflators, constant price estimates are seasonally adjusted using the same factors as are used for adjusting the corresponding current price estimates. As far as possible the remaining constant price estimates have been adjusted using methods similar to those for corresponding current price estimates.

12. Seasonally adjusted estimates of private final consumption expenditure for each State and Territory at current and average 1984-85 prices are shown in Tables 34 and 36 of this publication. Due to the relatively short span of data available for analysis, no Easter or trading-day correction factors have been applied in the seasonal adjustment of these series. The State and Territory series have been adjusted at a more aggregated level than the Australian series and independently of them (although as far as possible similar methods have been used). For these reasons the sum of the seasonally adjusted State and Territory series do not generally equal the seasonally adjusted Australian series.

13. Trend estimates are included in this publication. Smoothing seasonally adjusted series to create trend estimates is a means of reducing the impact of the irregular component of the series. Users may wish to refer to the ABS Information Papers *A Guide to Smoothing Time Series - Estimates of 'Trend'* (1316.0) and *Time Series Decomposition - An Overview* (1317.0) for more detailed information on smoothing seasonally adjusted time series data.

Analysis of contributions to growth table

14. Table 3 presents an analysis of the contribution provided by each major aggregate to the percentage change in seasonally adjusted gross domestic product at constant prices. The formula used to calculate the contribution of each aggregate to the growth in GDP is:

$$\frac{A(t) - A(t-1)}{GDP(t-1)} \times 100.0$$

where $A(t)$ = value of aggregate A in quarter under consideration

$A(t-1)$ = value of aggregate A in preceding quarter

$GDP(t-1)$ = value of GDP in preceding quarter.

All these values are seasonally adjusted constant price estimates. It should be noted that the figures in this table are additive within each quarter, unlike the percentage changes shown in other tables in this publication.

Terms of trade

15. There are several ways of measuring the terms of trade. A common means of doing so is by calculating an index of the form:

$$\frac{\text{Price index of exports}}{\text{Price index of imports}} \times 100.0$$

16. In this publication the price indexes used in calculating the terms of trade are the implicit price deflators for exports of goods and services and for imports of goods and services. They take into account not only the changes in the prices of exports and imports, but also the effects of changes in the composition of exports and imports on total recorded price movements. The terms of trade is presented as a memorandum item in Tables 4 and 9.

Gross domestic product (GDP) at constant prices, adjusted for the terms of trade

17. Changes in the aggregate 'gross domestic product at constant prices' provide an indication of changes in the volume of goods and services produced within Australia. If, however, the terms of trade have changed significantly over the period of comparison this aggregate will not provide an accurate reflection of the change in the real purchasing power of the income generated by domestic production.

18. As with the terms of trade, no single agreed measure of the effect of the terms of trade on movements in GDP at constant prices is available, and the available methods will generally produce different results.

19. In this publication the adjustment has been calculated by first revaluing exports of goods and services by the implicit price deflator of imports of goods and services (thereby providing a measure of the purchasing power of exports over imports). The actual constant price value of exports of goods and services has then been deducted from this value to provide the terms

of trade adjustment which has been added to GDP at constant prices to obtain the required result. The series is presented as a memorandum item in Tables 2 and 8.

Expenditure-based estimate of gross non-farm product

20. The published measure of GDP is the sum of the income components in the domestic production account. Alternatively, expenditure-based estimates of GDP and gross non-farm product can be produced by subtracting the statistical discrepancy from the published estimates. Expenditure-based estimates of gross non-farm product are presented as a memorandum item in Tables 2 and 8.

Private non-farm stocks to sales ratio

21. The denominator of this ratio is defined as gross non-farm product *plus* endogenous imports (imports of goods *excluding* imports of fuel, imports of certain large items of equipment by both the public and private sectors and certain other government imports) *plus* imports of services *less* changes in private non-farm stocks. All of these variables are at constant prices. The ratio is presented as a memorandum item in Table 8.

Imports to sales ratio

22. The ratio is endogenous imports to sales (both as defined for the private non-farm stocks to sales ratio - see paragraph 21). It is presented as a memorandum item in Table 8.

Household saving ratio

23. This is defined as the ratio of household saving to household disposable income, where household saving is a balancing item derived as the difference between household disposable income and private final consumption expenditure. The ratio is presented as a memorandum item in Table 23.

Data on floppy disk

24. All quarterly series included in this publication, with the exception of those included in the overseas trade tables, are available on floppy disk (*Australian National Accounts: Quarterly Data on Floppy Disk* (5228.0)). These data generally run from September quarter 1959 for current price estimates and from September quarter 1974 for constant price estimates. The cost is currently \$75 per release for most customers. Order forms for the service can be obtained by telephoning (06) 252 6684.

Related publications

25. In addition to those mentioned above, other ABS publications which may be of interest include:

Australian National Accounts: Historical Estimates (5207.0) - issued for December quarter only

Budget Related Paper No. 2, National Income and Expenditure (5213.0) - issued annually

Australian National Accounts: State Accounts (5220.0) - issued annually

Australian National Accounts: Capital Stock (5221.0) - issued annually

Australian National Accounts: Gross Product, Employment and Hours Worked (5222.0) - issued quarterly.

Australian National Accounts: Gross Product, Employment and Hours Worked (5211.0) - issued annually

Development of Multifactor Productivity Estimates for Australia, 1974-75 to 1987-88, Information Paper (5229.0)

A Guide to the Australian National Accounts (5235.0)

26. Current publications produced by the ABS are listed in the *Catalogue of Publications and Australian products* (1101.0). The ABS also issues, on Tuesdays and Fridays, a *Publications Advice* (1105.0) which lists publications to be released in the next few days. The Catalogue and Publications Advice are available from any ABS office.

Electronic services

DISCOVERY. Key *656# for selected current economic, social and demographic statistics.

AUSSTATS. Thousands of up-to-date time series are available on this ABS on-line service through PAXUS COMNET. Further information can be obtained by calling the AUSSTATS Help Desk on (06) 252 6017.

TELESTATS. This service provides:

- foreign trade statistics tailored to users' requirements.
Further information is available on (06) 252 5404.
- text and tables for selected Main Economic Indicator publications
Further information is available on (06) 252 5405.

Floppy disk service

Selected ABS statistics are available on floppy disk. Further information is available on (06) 252 6684.

FEATURE ARTICLE:**NATURAL RESOURCE AND
ENVIRONMENTAL ACCOUNTING
IN THE NATIONAL ACCOUNTS**

Introduction

1. This article discusses the treatment of natural resources and environmental issues in the national accounts, and considers the criticisms put forward by environmental economists and others of the existing treatment. Some alternative approaches which have been proposed are examined. Possible future developments in accounting for environmental factors in the Australian national accounts are also outlined.

2. Environmental concerns may be categorised as follows:

- depletion and extension of natural resources;
- conservation of the environment; and
- the effects of pollution and its control.

3. Although this categorisation in effect sets the conceptual scope of natural resource and environmental accounting, it should be noted that no country has as yet set up accounts, either within or outside the national accounting framework, to encompass all of these issues.

4. While this paper is primarily concerned with the treatment of natural resources and environmental issues within the national accounting framework, this need not be the only approach to the development of environmental statistics. For example, one would initially expect to see the development of an array of indicators of change in environmental conditions and in activities affecting the environment. These might be in aspects as diverse as agricultural practices, monitoring the use of funds, and trends in recycling materials and in the impact on the environment of various forms of transport. Indicators of this kind would be of interest in their own right but might also be used in compiling environmental accounts. This would be analogous to the relationship between indicators of economic activity and the set of conventional economic accounts.

Development of national accounting

5. National accounts in their modern form evolved from the publication of Keynes' General Theory and the interest by governments during World War II and the early post-war period in production and allocation of resources to competing uses.

6. The major preoccupation of economists at the time was in building a statistical model of the workings of the economy, using the relationships postulated by Keynes, in order to develop prescriptions for a high and stable level of economic activity.

7. At their summary level the national income and expenditure accounts were designed to reflect the economic flows of the Keynesian system:

production, consumption, investment and saving. The present national accounts still reflect this basic system of identities.

8. In recent years, a number of economists have come to the view that the conventional national accounts framework should be modified or extended to take into account such factors as the extent of renewability and the rate of depletion of natural resources, and of changes in the quality of the environment.

National accounts framework

9. The national accounts provide a systematic statistical framework for summarising and analysing the economic transactions taking place within the nation. A complete set of national accounts includes a number of flow accounts and a balance sheet. The flow accounts measure production, the incomes flowing from that production, both real and imputed, and capital transactions over a given time. The balance sheets record the levels of assets, liabilities and net worth at a particular point in time. The flow accounts and balance sheets are linked in that the stocks of assets and liabilities are equal to accumulated past capital transactions after allowing for revaluations and the creation and retirement of assets and liabilities. Australia has a full set of production and income accounts and is currently extending its capital transactions accounts to include flows of funds. As yet it has not compiled balance sheet accounts because of the significant estimation problems involved and the lack of data for some parts of the balance sheets. In addition, the overwhelming interest of economic policy makers in the past half-century has been in current income flows.

10. The international standard for national accounting is the United Nations 'A System of National Accounts' (the SNA), issued in 1968¹. The Australian national accounts are based on this system. The SNA deals only briefly with balance sheets. An elaboration of the part of that system relating to balance sheets is contained in United Nations Statistical Papers Series M.No.60 (known as M60)², which was issued in 1977 to provide provisional international guidelines.

Balance sheets and reconciliation accounts

11. Balance sheet accounts are defined as 'statements of tangible assets and intangible non financial assets derived by the various institutional sectors of the economy and of the outstanding financial claims between institutional units'³.

12. Balance sheets measure national wealth, including the level of tangible assets which are made up of human-made assets and assets of the natural environment, or as M60 defines them, reproducible and non-reproducible tangible assets. The former

1 United Nations, *A System of National Accounts*. Publication E. 69.XV11.3, New York, 1968.

2 United Nations, *Provisional International Guidelines on the National and Sectoral Balance Sheet and Reconciliation Accounts of the System of National Accounts*. Series M, No. 60., E.77.XVII,10., New York, 1977.

3 M.60, p.5.

include the fixed assets and stocks of enterprises, financial institutions, government entities and private non-profit institutions. The latter include land, timber tracts and forests, subsoil deposits and historical monuments.

13. Within the SNA framework, balance sheet accounts are linked to the flow accounts by capital finance accounts, which portray a significant part of the changes between opening and closing levels of assets and liabilities. Those changes in assets and liabilities, such as net additions to the stock of natural assets, revaluations and unforeseen events, which are not included in the capital finance accounts of the SNA, are recorded in what are called the 'reconciliation accounts'. As those changes are also excluded from the production and income and outlay accounts, they do not affect the level of national income of the intervening period. They simply represent the changes in the value of net assets between successive measurement dates that are not attributable to transactions.

14. The principal exclusion from balance sheet accounts relates to resources in the public domain which are not subject to ownership rights and are thus generally not sold or purchased (e.g. rivers, lakes, parklands, unused wilderness and the atmosphere). This is consistent with the scope of the SNA which is generally limited to market activities (except for imputations for directly competitive non-market activities). Even if it were considered desirable to include these resources from the point of view of obtaining a more complete measure of the national estate, measurement problems would make their inclusion difficult in practice. Only those natural resources which are commercially traded or used in the production of goods and services that are priced in the market place can be readily valued. However, outlays on the permanent improvement and extension of natural resources in the public domain are considered within scope of the flow accounts of the SNA because their provision generates economic activity. They are covered in capital formation, thereby increasing the reproducible tangible assets (classified as 'other construction works' or 'land improvements') in the balance sheet accounts.

15. The initial expenditure to establish naturally growing but commercially traded assets, such as timber tracts, plantations and fisheries, is counted as capital formation in the flow accounts of the SNA. Further growth and depletion are not recorded as capital formation but are included in the reconciliation accounts. Both the creation of assets and subsequent increases or decreases affect the level of tangible assets recorded in the balance sheet accounts.

16. The reconciliation accounts are particularly relevant for natural resources. The items recorded in these accounts are categorised as follows:

- revaluations of assets due to price changes;

- net adjustments to the stock of assets due to unforeseen events (mainly premature retirements of assets because of early obsolescence as a result of technology changes);

- net increases in the value of tangible assets not accounted for in the capital finance accounts (such as changes in the existing stock of natural resources);

- net adjustments to the stock of assets due to changes in their structure and classification; and

- statistical discrepancies and discontinuities (representing the residual difference between opening and closing balance sheet positions).

17. The item 'net increases in the value of tangible assets not accounted for in the capital finance accounts' is directly relevant to natural resources accounting. It includes natural growth less depletion of timber tracts, forests and fisheries; new finds less depletion of subsoil assets; and losses in land and timber tracts in catastrophes such as bushfires. It excludes, however, changes in land quality due to erosion, waterlogging, desertification, salinisation or upgrading; and increased availability of mineral resources due to technological advances. These latter changes are recorded as changes in the market value of land and subsoil assets – part of the revaluations item of the reconciliation accounts.

18. A number of problems exist within the UN's stated guidelines for balance sheets. First, it could be argued that resources in the public domain are part of the wealth of a country and should be included within scope. M60 appears to exclude them on the pragmatic grounds of "the conceptual and practical difficulties of valuing...[such] assets"⁴, i.e. they are excluded because they cannot be satisfactorily valued. Some examples of such exclusions are beaches, native flora and fauna, fish stocks within a nation's fishing zone and subsurface water.

19. Second, the UN balance sheet guidelines are deficient in that they do not provide for the separate identification of the extensions and depletions elements of a net change.

20. Third, implementation of the guidelines would pose further problems. Physical and monetary data for those non-reproducible assets within scope are poor and, in some cases, non-existent. Even where physical units exist, the problem of valuation remains. Given this constraint, there is an argument for data on the quantity of reserves to be presented separately within the balance sheets.

21. Guidelines are provided in M60 for the valuation of tangible non-reproducible assets. The two principal approaches are:

- the use of values derived from market transactions in assets; and

- when such values are not available, the use of the discounted present value of estimated future income flows derived from the assets to be valued. This method consists of valuing assets from which the returns are either delayed or spread over a lengthy period. The main problem with such an approach is choosing the appropriate rate of discount.
22. Considerable valuation problems would have to be resolved before Australia could produce a full set of balance sheet and reconciliation accounts. At present, Australia does compile two important elements of balance sheets, namely stocks of fixed assets and the international investment position. However, the former refers to 'human-made' rather than natural resource assets and the latter is restricted to financial claims between Australia and the rest of the world.
23. The framework for balance sheets as outlined in M60 has attracted less adverse comment from environmental economists than the exclusion of most environmental factors from the current measure of GDP. However, the fact that most countries have not yet fully implemented the balance sheet guidelines, particularly in respect of natural resources, has been noted as a major deficiency of national accounting systems. Given the emphasis on the national income accounts, the treatment of natural resources in these accounts is now discussed.
- ### National income accounts
24. National income accounting measures economic production. Production is the process whereby labour, natural resources, accumulated capital assets and knowledge are applied to the provision of goods and services. Gross domestic product (GDP) is the most commonly used measure of aggregate income, or product.
25. The national income accounts concentrate on the role of capital and labour in the production process. Natural resources have a passive role in that they are regarded as gifts of nature with a zero supply price. Implicit is the notion that, as no dollar costs are incurred in their provision, nothing needs to be deducted from current income as resource stocks are depleted. Also, the conceptual approach adopted in the national accounts does not envisage that the disposal of wastes from the production process imposes any cost on the environment.
26. However, any income-generating activity which flows from exploiting these assets does enter the national income and expenditure accounts. Sales of minerals are included on the expenditure side, explicitly in exports and implicitly in the final value of various goods and services sold (they are also shown explicitly within the 'increase in stocks' item); on the income side, the value added from mineral extraction is included in wages, salaries and supplements, and in the gross operating surplus of enterprises.
27. The origins of the existing national accounts concept of income lie in the history of the models of economic activity which have developed.
28. The classical economists regarded income as the return on three kinds of assets: natural resources, human resources (labour) and invested capital. However, the neoclassicists, from whom modern twentieth century economic theory is derived, dropped natural resources from their model to concentrate on capital and labour. The implied premise was that natural resources were in infinite supply or were capable of regeneration.
29. This premise has come under increasing challenge in recent times. Environmental economists have called for a reconsideration of the basic concepts of production and income. Specifically, they have taken issue with the concept of income used in national income accounting because it does not measure 'sustainable income'.
30. Sustainable or 'true' income, as defined by Adam Smith and later clarified by Hicks, is the maximum value that a person can consume during a period and still expect to be as well off at the end of the period as at the beginning. In other words, sustainable income is the maximum amount that can be consumed in a given period without reducing the amount of possible income in the future. It is not really practicable to measure Hicks' concept of sustainable income in national income and expenditure accounts. Balance sheets would provide the best means of producing a measure of Hicks' 'true income'.
31. Conceptually, national accounting definitions of income at present do not approximate Hicks' idea of income. First, no deduction has been made from GDP for the capital that is consumed during a particular period. This is quite deliberate as the 'gross' in GDP implies. National accountants have always recognised that a product figure net of capital consumed (i.e. net domestic product) would be a purer measure of income and production but because of difficulties in measuring capital consumption, and because the major emphasis has been on actual income flows, GDP has remained the most commonly used summary measure of economic activity.
32. Second, the capital that is consumed to arrive at the measure of net domestic product (which better approximates Hicks' notion of income) is only the fixed capital component of the economy's productive assets. Natural resource assets, which also contribute to income in future periods, are ignored just as in the neoclassical model. The resulting aggregate, according to environmental economists, overstates the maximum net product available for consumption. (However, it is noteworthy that this is not the only area which is excluded in this way. Both advances in technology and the level of skills of the population are important productive assets which are not measured in the national accounts.) Some economists claim that the policy advice which results from ignoring natural resource assets encourages over consumption of natural resources to the detriment of the long term sustainability of economic activity. It should be noted that net domestic product is not explicitly shown in the Australian national accounts (ANA). However, a similar concept, national income, is measured. It is defined as net domestic product (i.e.

GDP less consumption of fixed assets) less net income paid overseas.

33. Third, a point sometimes overlooked in the literature is that Hicks' notion of income also implies that net extensions to the resources base should be added to income. New discoveries of oil for example, would show up as a large increase in income in the period in which they were discovered. Substantial new finds would distort annual movements in income. Such a concept of income would have severe shortcomings for economic policy concerned with short term stabilisation. This leads to the further point that no single concept of income is suitable for all analytical and policy uses.

34. Two principal adjustments have been recommended in the literature to move the national accounts closer to a concept of sustainable income.

35. The first has been to extend the concept of depreciation to cover consumption of natural resources through degradation and depletion. The second is to subtract from GDP so-called 'defensive expenditures' i.e. expenditures undertaken to protect the environment from damage incurred during economic activity.

Degradation and depletion of natural resources

36. Many commentators argue that the central problem with the current SNA is that it treats the depreciation of human-made assets differently from that of natural resource assets. National income only accounts for the consumption of human-made assets, by writing them off against the value of production as they depreciate over their lifetime. The depletion of natural resource assets, however, produces no debit charge against current income to reflect the decrease in potential future production. Instead, in theory, the depletion is reflected in the balance sheets of the national accounting system. For example, in the words of Robert Repetto, a leading resource economist with the World Resources Institute, "a country could erode its soil, extract its minerals, cut down its trees but measured income would be unchanged as these resources disappeared".⁵ An example of a country in such a situation is Nauru which has been heavily dependent on its phosphate deposits for its economic growth in the last few decades. However, growth from that source is not sustainable because the natural resource being exploited is rapidly being depleted. In national balance sheets, however, this situation would be identified by the decline shown in the country's net worth.

37. Two main conceptual approaches have been suggested to better deal with the depletion and degradation of natural resources and the environment in the national accounting framework: the depreciation approach and the user cost approach. The latter was developed by Salah El Seragy, a World Bank economist, to account for an apparent confusion between income and capital which, he argues, exists with the depreciation approach.

Depreciation approach

38. In the depreciation approach, the concept of depreciation of human-made capital is applied to the consumption of natural resource capital. The resultant estimate is deducted from GDP (as currently defined), along with the consumption of fixed capital to form NDP. (Using this procedure results in no change in the level of GDP but potentially significant reductions in NDP compared with present estimates.) Although the broad principle seems clear, a number of details at both the theoretical and practical level have to be resolved. For example, should the deduction to derive NDP include only depletions or should it relate to net depletions, i.e. additions to resource stocks less depletions? Should revaluations due to price changes be included? If additions are included, growth in NDP may actually be greater than that in GDP in some years. For resources that are sold, the depreciation factor (i.e. the economic rent attributable to the ownership of that resource) can be estimated as the value of sales less costs of extraction (i.e. intermediate expenses and labour and capital costs including a normal return to capital).

39. Ideally, reserves of mineral resources should be valued at the market prices at which the natural resource asset would currently change hands if sold in its entirety. However, because most resource stocks are unlikely to be the subject of a current market transaction, an alternative means of valuation is required. Two methods have been proposed:

- the net present value of future net returns; or
- the net price, or unit rent, of the resource multiplied by the relevant quantity of the reserves.

40. The *net present value* method, recommended by the United Nations Statistical Office, requires that future prices, operating costs, production levels, and interest rates be forecast over the life of the reserves (for example, a given oil field) at the time of their discovery. The present value of the stream of net revenue is then calculated, representing the total revenue from the resource less all extraction costs. The *net price* method, adopted by the private accounting bodies in the USA for oil and gas stocks, applies the prevailing average net price per unit of the resource (calculated as current revenues less current production costs per unit) to the physical quantities of proven reserves in order to derive changes in the levels of proven reserves. It is a much simpler method than the former.

41. Despite the existence of estimation and data problems, environmental economists argue that it is better to make some allowance for the use of natural resources than to make none at all. They acknowledge that some estimates may be rather arbitrary, but note that a degree of approximation is already required in the estimation of depreciation of human-made capital and in other national accounting aggregates, such as the imputed rent of owner-occupied dwellings.

5 R. Repetto et al, *Wasting Assets, Natural Resources in the National Income Accounts*, World Resources Institute, 1989, p.2.

42. It should be noted that, because reserves of some natural resources such as coal, iron ore and bauxite are so extensive their present economic rents are quite low even though the level of extraction is reasonably high. In these circumstances, it would make little difference whether or not net changes in stocks are recorded as a deduction from (or an increase in) NDP.

43. Salah El Serafy rejects the depreciation approach on conceptual grounds. He writes: "If we deduct from the gross receipts from the mineral sales in any one year an amount equal to the depletion along the lines described above, the value of *net income* from this activity becomes zero. Where a country derives 100 percent of its receipts from, say, petroleum extraction – an extreme case of a Saudi Arabia – the depreciation approach (ignoring the multiplier effect of ancillary activities related to extraction as well as the contribution of other sectors to value-added) would give us a GDP of 100 and a NDP of zero – a measurement that is not particularly edifying". He suggests that the depreciation approach is flawed because it deducts the whole of gross product from the gross receipts. However, his views seem to rest on an extreme interpretation of the depletion factor. They do not accord with those of most environmental economists who consider that economic rent (as defined in paragraph 38 above) should be adopted as the depletion factor. He therefore recommends the user-cost approach to overcome problems with the depreciation approach.

User cost approach

44. The user cost approach modifies the measurement of the depletion factor which, in the depreciation approach, potentially wipes out all the growth in activity from the net product or causes large swings in the growth rate when new reserves are discovered. It attempts to split, net of extraction cost, the revenue from the sales of a depletable resource into a capital element, or user cost, and a value added element representing true income. The capital element represents asset erosion, which could be reinvested (if the owner wanted) to generate sufficient future income, to maintain the present level of true income as the resource is being depleted and long after the original resource has been exhausted. This part (asset erosion) should be excluded from both GDP and NDP. The value added element on the other hand should be included in GDP and NDP. Therefore the user-cost approach, unlike the simpler depreciation approach, alters the level of GDP itself.

45. The concept behind the user cost approach is to calculate that part of total receipts attributable to true income. In practice, a discount rate is applied to the total receipts over the whole life of the resource. It involves calculating the amount of income which would have to be invested in each period to maintain the same income in each period while the resource is being used and after it is entirely used up. Assumptions have to be made about the reserves-to-extraction ratio (i.e. the life expectancy of the resource measured in years) and the discount rate.

For example, a country which liquidates its reserves of a particular resource over fifty years needs to set aside for reinvestment a smaller portion of its receipts than another which liquidates its reserves over twenty years and can thus count a larger portion of its receipts as current income. Similarly, the higher the discount rate, the higher is the proportion of receipts allocated to current income.

Defensive expenditure

46. The national accounts treatment of expenditures incurred to defend the environment against damage by economic activity has also attracted attention from environmental economists. These expenditures are undertaken to mitigate the unwanted side effects of production and consumption. They are made to compensate for, redress or guard against losses of environmental functions relating to land, air and water. They include expenditures on pollution abatement, soil conservation, air and water quality monitoring, water and sewerage treatment, waste disposal, and cleaning up pollutants from the environment. Expenditures on the prevention of, and compensation for, environmental losses do not contribute to the quantity of goods available for consumption; they simply protect or replace scarce environmental goods that were already available. They can be viewed as a cost of economic activity and it has therefore been suggested that they should not contribute to the level of sustainable income or production.

47. Environmental economists regard the treatment of defensive expenditure in the national accounts as unsatisfactory because this expenditure actually adds to the level of measured income in many cases. Defensive expenditures are treated differently in the national accounts depending on the economic agents undertaking the expenditure. Government sector output is calculated as the sum of wages paid and material inputs used. Therefore, government expenditures on the environment are measured as purchases of final goods and services (of either a current or capital nature). As a result, measured income and expenditures will rise if there is an increase in government expenditure on protecting the environment. For example, if the government is involved in a major clean up of the environment after, say, a major oil spill, measured income will be seen to rise at the same time as there has been a deterioration in (or at best a partial reinstatement of) the natural environment.

48. The impact on measured income of defensive expenditures by industry is a little less certain. Current expenditures are treated as intermediate consumption and therefore, at least initially, do not directly add to income. They are reflected instead as a cost, resulting in a lower gross operating surplus of the industry concerned. However, in practice it is reasonable to assume that the costs of ongoing defensive expenditures, such as for pollution abatement, will be reflected to some extent in the price of goods sold. The impact on measured income in current price terms will depend on the elasticity of demand for the particular good or

6 Salah El Serafy, *The Proper Calculation of Income from Depletable Natural Resources*, in Y.J. Ahmad, S. El Serafy, E. Lutz (eds.), *Environmental Accounting for Sustainable Development*, The World Bank, Washington D.C., 1989, p.13.

service in question and therefore expenditure may not detract significantly from measured income. On the other hand, in the case of irregular expenditures, say for environmental clean-up after the release of pollutants, it would be reasonable to assume that such costs are not passed on, unless the business is in a monopoly position. Defensive expenditures of a capital nature, such as the purchase by industry of equipment to inhibit the release of pollutants, are treated as final expenditure.

49. One problem with changing the treatment of defensive expenditure is where to draw the line. There are many other final expenditures not directly related to the natural environment but which are not associated with an increase in goods available for consumption, (e.g. expenditures on national defence). Given that the purpose of defence is to maintain the status quo, any such expenditure does not result in an increased availability of goods for consumption, yet measured income rises if defence expenditure increases.

50. It should also be noted that the exclusion of defensive expenditure from GDP would have consequences for the accounts that go beyond the reclassification of these expenses from final expenditure to intermediate expenditure. The wages and salaries and gross operating surplus flowing from these expenditures would also have to be identified in some way so that they could be deducted to preserve the identity that GDP can be measured by summing either incomes, gross output less intermediate expenditures, or final expenditures plus exports less imports.

51. A further practical problem is that pollution abatement expenditure can be notoriously hard to define from a statistical collection point of view. While businesses may know how much they have spent to comply with recent government regulations, they will probably not be able to identify (or even be aware of) their total expenditures on pollution abatement. Also there is the difficulty of separating out the cost of new plant purchases into the component relating to pollution abatement and that relating to production of goods and services.

Review of SNA and developments in resource accounting

52. The SNA is currently undergoing an intensive revision in the light of the experience of countries and international agencies in its use over the twenty years or so since the release of the 1968 version. The revision of the SNA is being managed by a group consisting of members of the United Nations Statistical Office, the IMF, the World Bank, the Statistical Office of the European Communities and the OECD. A number of expert group meetings have been held, which will culminate in the production of a redrafted SNA. It has already been decided by the experts involved in the revision process that no major conceptual changes should be introduced into the SNA.

53. The experts acknowledge that the current system has many shortcomings with respect to environmental and natural resource accounting but consider that it is not yet feasible to replace existing concepts of income with the concept of sustainable income. The existing system is a well-established system of data collection and accounting that serves many different short, medium, and long term socioeconomic analyses. Before specific recommendations can be made for changes to the core of the SNA to better incorporate the environment, it is the view of the national accounts experts that some outstanding conceptual issues need to be resolved, and a lot more empirical work has to be undertaken.

54. However, a consensus has emerged in recent expert group meetings that enough progress has been made to link environmental accounting to the core of the SNA by means of 'satellite accounts'. Such a system would allow specific areas of social concern to be analysed, without overburdening or disrupting the 'core' system. The satellite accounts would provide measures of defensive expenditures and of the use, depletion and degradation of natural resources. This would enable aggregate indicators of environmentally adjusted and/or sustainable income and product to be produced. The satellite accounts would also link physical resources with monetary environmental measures and balance sheets. The view of the national accounts experts is that further consideration could be given to adjusting the core of the SNA once adequate experience has been gained with these types of accounts and when various conceptual and valuation issues have been resolved.

55. A 'Draft Framework' for a proposed set of environmental satellite accounts was presented at the Twenty-First General Conference of the International Association for Research in Income and Wealth in August 1989⁷. It drew heavily on earlier work on this topic by Bartelmus and Van Tongeren and took into account suggestions made at meetings held in November 1988 and January 1989. Further discussion on this topic is scheduled for a meeting of national accounts experts to be held in Paris in July 1990. The Framework follows as closely as possible the framework established in the SNA. It segregates all flows and stocks of assets in the national accounts related to environmental issues, allowing the production boundary of the SNA to be adjusted to cover only non-environmental activities. This facilitates direct comparison of original (unadjusted) SNA data with environmentally adjusted indicators and better integrates environmental variables into established economic analysis.

56. Specifically the Framework focuses on:

- "— the use of natural resources in production and final demand, adjusting the concepts of intermediate and final consumption, value added, capital consumption and formation and introducing a broader concept of wealth accumulation;

7 P. Bartelmus, C. Stahmer, and J. Van Tongeren, *SNA Framework for Integrated Environmental and Economic Accounting*, presented to Twenty-first General Conference of the International Association for Research in Income and Wealth, West Germany, August 1989.

- the degradation of environmental quality (from pollution and other impacts of production, consumption and natural events); and
- the treatment of expenditures for environmental protection".⁸

57. Two groups of tables are articulated in the Framework. The first group shows the supply and use of goods and services, by industry, with the separate identification of environmental protection services from other production activities. The second group comprises the opening and closing balance sheets and two tables linking them - a table on volume changes in tangible wealth and a table on revaluation of assets.

58. The Framework outlines the calculation of various environmentally adjusted indicators. The first, 'environmentally adjusted GDP', is obtained by subtracting the environmental protection services (defensive expenditures) of governments and households from GDP. This reflects the fact that the Framework treats the environmental protection services of households and governments as the intermediate consumption of these sectors whereas the SNA currently includes them as final consumption by those sectors. The defensive expenditures of industry are already included in intermediate consumption when deriving unadjusted GDP.

59. Another indicator is 'sustainable gross domestic product' (SGDP), which is the difference between environmentally adjusted GDP and environmental costs. (Environmental costs result from the quantitative depletion of natural resources and the degradation of environmental quality by economic activities and from "natural or multiple causes".) It should be noted that additions/extensions to the natural resource base are not included in income but are only taken account of as they are exploited. Sustainable net domestic product is obtained by deducting the depreciation of fixed human-made capital from SGDP.

60. It is envisaged that the Framework will be developed into a draft manual and applied to several developing countries and perhaps one or two industrial countries in the form of pilot studies and/or in-depth case studies. This process will highlight potential problems at the conceptual, practical and policy-making levels. Subsequent reviews of the proposed manual by expert national accountants can be expected to lead to the publication of a handbook in the handbook series of the SNA. Developmental work on physical resource accounting already begun by United Nations Environment Programme (UNEP) will be continued, with emphasis on assessing the environment and natural resource base, its changes in quantity and quality, and its linkage to monetary accounting.

61. Developmental work on other aspects of natural resource accounting is also planned by a number of international agencies. This work is to be undertaken co-operatively by the World Bank, the

UN Statistical Office (UNSO), the United Nations Development Programme (UNDP) and UNEP, along with non-governmental organisations and developing-country governments.

62. Several industrial countries are already currently developing natural resource accounting systems. Robert Repetto has reviewed international activity in natural resource accounting.⁹ Norway and France have developed extensive systems of natural resource accounts as a supplement to the system of national accounts. Norway has compiled accounts in physical units for 'material resources' such as fossil fuels and other minerals, and for 'biotic resources' such as land, water and air. The French system includes cultural heritage in addition to natural resources. The accounts are in physical units, with provision for monetary valuation for stocks and flows that are marketed. In Japan and the US, development of estimates of pollution and environmental quality have taken priority over development of estimates of natural resource stocks. Canada and the Netherlands are also developing systems of environmental accounting. However, it should be noted that no countries actually adjust their national income accounts for the depletion of (or additions to) their natural resources.

Conclusion

63. While recognising the interest in adjusting major aggregates in the national accounts so that the sustainability of economic growth can be assessed, it also needs to be said that there is no single indicator which can describe all aspects of the well-being of a country's citizens. National accounting measures such as national income or GDP are major indicators of economic activity but there are significant aspects of the 'quality of life' which cannot be comprehended in a system of economic accounts, just as there are significant aspects of an individual's well-being which are not measured in the conventional concept (or any other concept) of that individual's income.

64. Notwithstanding their limitations, especially in relation to uses for which they were never designed, the national accounts provide vital information for a range of important purposes. The conventions followed in compiling them are fully articulated. They have been developed and refined over the course of the past half-century, by experts who understand that there are many questions which cannot be answered by any system which relies solely on the measuring rod of money (even though techniques are available for removing the effects of changes in the value of money). The system of national accounts provides a framework or structure which can be, and has been, adapted and extended to facilitate the examination of various economic and social policy issues. Environmental and natural resource issues can also be accommodated within this framework.

65. Even if debates about conceptual and valuation problems can be resolved, there are problems involved in obtaining accurate and reliable data on

⁸ *Ibid.* p. 4.

⁹ R. Repetto et al, *op.cit.* pp. 14-15.

levels of stocks of natural resources and the magnitude of the factors which impact upon those stock levels from year to year. Despite these difficulties, the ABS considers that such satellite accounts would provide an important supplement to the national accounts.

66. The advantages of setting up satellite accounts are that:

- they would be compiled within the internationally recognised (and used) SNA framework;
- as a result, they could be interpreted in conjunction with the best available measure of overall economic activity – the national income accounts; and

• the lack of consistent data over time would not impact directly on the quality of the existing accounts, which are important tools for economic policy makers.

67. The ABS is taking a close interest in developments in environmental and natural resource accounting and it recognises the growing need for a comprehensive means of assessing whether or not the current rate of economic development is sustainable in the longer term. The ABS is planning to investigate the emerging statistical requirements in this area and to put further effort into improving the statistical measures available on Australia's natural resources and environment.
